1 Introduction

2 Motivation

3 Resolution

4 Cases & Examples

5 Conclusions

Notation and Assumptions

- $\bar{x} = 1 - x$.
- **Probabilistic Atomic Choice (PAC):** $\alpha :: a$ defines $a \vee \neg a$ and probabilities $p(a) = \alpha, p(\neg a) = \bar{\alpha}$.
- δa denotes $a \vee \neg a$ and $\delta\{\alpha :: a, a \in \mathcal{A}\} = \{\delta a, a \in \mathcal{A}\}$ for a set of atoms \mathcal{A} .
- **Closed World Assumption:** $\sim x \models \neg x$.

General Setting

- **Atoms** \mathcal{A} , $\overline{\mathcal{A}} = \{\neg a, a \in \mathcal{A}\}$,
- **Inputs** \mathcal{Z} :

$$\mathcal{Z} = \left\{ z = \alpha \cup \beta, \alpha \subseteq \mathcal{A} \wedge \beta \subseteq \overline{\mathcal{A}} \right\}$$

- **Interpretations** or *consistent inputs* \mathcal{I} :

$$\mathcal{I} = \left\{ z \in \mathcal{Z}, \forall a \in \mathcal{A} \mid |\{a, \neg a\} \cap z| \leq 1 \right\}.$$

- **PASP Problem** or **Specification**: $P = C \wedge F \wedge R$ where
 - $C = C_P = \{\alpha_i :: a_i, i \in 1 : n \wedge a_i \in \mathcal{A}\}$ *facts*.
 - $F = F_P$ *facts*.
 - $R = R_P$ *rules*.
 - $\mathcal{A}_P, \mathcal{Z}_P$ and \mathcal{I}_P : *atoms, inputs and interpretations* of P .
- **Stable Models** of P , $\mathcal{S} = \mathcal{S}_P$, are the stable models of $\delta P = \delta C + F + R$.

Distribution Semantics

- **Total Choices:** $\Theta = \Theta_C = \Theta_P$ elements are $\theta = \{t_c, c \in C\}$ where $c = \alpha :: a$ and t_c is a or $\neg a$.
- **Total Choice Probability:**

$$p(\theta) = \prod_{a \in \theta} \alpha \prod_{\neg a \in \theta} \bar{\alpha}. \quad (1)$$

This is the *distribution semantic* as set by Sato.

Problem Statement

How to *extend* probability from total choices to stable models, interpretations and inputs?

There's a problem right at extending to stable models.

The Disjunction Case

Disjunction Example

The specification

$$0.3 :: a, \\ b \vee c \leftarrow a.$$

has three stable models,

$$s_1 = \{\neg a\}, \quad s_2 = \{a, b\}, \quad s_3 = \{a, c\}.$$

- Any stable model contains exactly one total choice. ■
- $p(\{\neg a\}) = 0.7$ is straightforward.
- But, no *unbiased* choice for $\alpha \in [0, 1]$ in

$$p(\{a, b\}) = 0.3\alpha,$$

$$p(\{a, c\}) = 0.3\bar{\alpha}.$$

Lack of Information & Parametrization

- The specification *lacks information* to set $\alpha \in [0, 1]$ in

$$p(\{a, b\}) = 0.3\alpha,$$

$$p(\{a, c\}) = 0.3\bar{\alpha}.$$

- A *random variable* captures this:

$$p(\{\neg a\} \mid A = \alpha) = 0.7,$$

$$p(\{a, b\} \mid A = \alpha) = 0.3\alpha,$$

$$p(\{a, c\} \mid A = \alpha) = 0.3\bar{\alpha}.$$

- Other uncertainties lead to further parameters:

$$p(s \mid A_1 = \alpha_1, \dots, A_n = \alpha_n).$$

Reducing **specification uncertainty**, e.g. setting $A = 0.21$, must result from **observations**.

Main Research Question

A *random variable* captures this:

$$p(\{\neg a\} \mid A = \alpha) = 0.7,$$

$$p(\{a, b\} \mid A = \alpha) = 0.3\alpha,$$

$$p(\{a, c\} \mid A = \alpha) = 0.3\bar{\alpha}.$$

Main Research Question

Can *all* specification uncertainties be neatly expressed as that example?

- Follow ASP syntax; for each case, consider the possible uncertainty scenarios.
- The disjunction example illustrates one such step.

⑤ Conclusions

Specification, Data & Evaluation

Given some procedure to extend probabilities to stable models, interpretations and inputs, and given:

- P , a specification.
- p , the distribution of inputs from above.
- Z , a dataset of inputs.
- e , the respective empirical distribution.
- D , some probability divergence, e.g. Kullback-Leibler.

*For a dataset Z , $D(P) = D(e, p)$ is a **performance** measure of P and can be used, e.g. as fitness, by algorithms searching for **optimal specifications of a dataset**.*

- 1 Introduction
- 2 Motivation
- 3 Resolution**
- 4 Cases & Examples
- 5 Conclusions

Resolution Path

- ① *Parametrize* lack of knowledge e.g. α in the disjunction example.
- ② This extends probability from total choices to *standard models*.
- ③ Extend probability from standard models to *interpretations*.
How? Later.
- ④ Set $p(z) = 0$ for $z \in \mathcal{Z} \setminus \mathcal{I}$.

Bounds of Interpretations

- For $x \in \mathcal{I}$:
 - **Lower Models:** $\langle x | = \{s \in \mathcal{S}, s \subseteq x\}$.
 - **Upper Models:** $|x \rangle = \{s \in \mathcal{S}, x \subseteq s\}$.
- **Proposition.** Stable models are *minimal* so *one* of the following cases takes place:
 - ① $\langle x | = \{x\} = |x \rangle$ and x is a stable model.
 - ② $\langle x | \neq \emptyset \wedge |x \rangle = \emptyset$.
 - ③ $\langle x | = \emptyset \wedge |x \rangle \neq \emptyset$.
 - ④ $\langle x | = \emptyset = |x \rangle$.

Next we try to formalize the possible configurations of this scenario. Consider the ASP program $P = C \wedge F \wedge R$ with total choices Θ and stable models \mathcal{S} . Let $d :: \mathcal{S} \rightarrow [0, 1]$ such that $\sum_{s \in \mathcal{S}_\theta} d(s) = 1$.

① For each $z \in \mathcal{Z}$ only one of the following cases takes place

① z is inconsistent. Then **define**

$$w_d(x) = 0. \quad (2)$$

② z is an interpretation and $\langle z | = \{z\} = |x\rangle$. Then $z = s$ is a stable model and **define**

$$w_d(z) = w(s) = d(s) p(\theta_s). \quad (3)$$

③ z is an interpretation and $\langle z | \neq \emptyset \wedge |x\rangle = \emptyset$. Then **define**

$$w_d(z) = \sum_{s \in \langle z |} w_d(s). \quad (4)$$

④ z is an interpretation and $\langle z | = \emptyset \wedge |z\rangle \neq \emptyset$. Then **define**

$$w_d(z) = \prod_{s \in |z\rangle} w_d(s). \quad (5)$$

⑤ z is an interpretation and $\langle z | = \emptyset \wedge |z\rangle = \emptyset$. Then **define**

$$w_d(z) = 0. \quad (6)$$

② The last point defines a “weight” function on the inputs that depends not only on the total choices and stable models of a PASP but also on a certain function d that must respect some conditions. To simplify the notation we use the

 - Non-stratified programs
- 5 Conclusions

Consider the program:

$$c_1 = a \vee \neg a,$$

$$c_2 = b \vee c \leftarrow a.$$

This program has two total choices,

$$\theta_1 = \{\neg a\},$$

$$\theta_2 = \{a\}.$$

and three stable models,

$$s_1 = \{\neg a\},$$

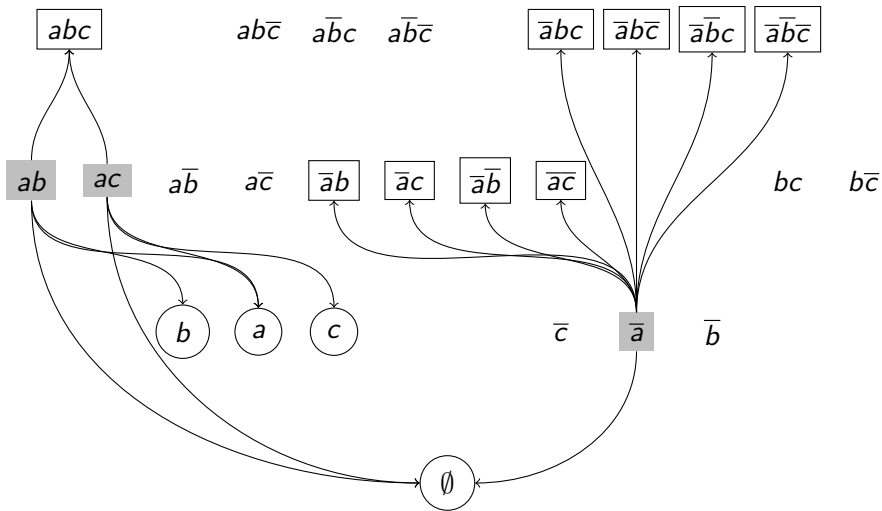

$$s_2 = \{a, b\},$$

$$s_3 = \{a, c\}.$$

Suppose that we add an annotation $\alpha :: a$, which entails $\bar{\alpha} :: \neg a$. This is enough to get $w(s_1) = \bar{\alpha}$ but, on the absence of further information, no fixed probability can be assigned to either model s_2, s_3 except that the respective sum must be α . So, expressing our lack of knowledge using a parameter $d \in [0, 1]$ we get:

$$\begin{cases} w(s_1) = \bar{\alpha} \\ w(s_2) = d\alpha \\ w(s_3) = \bar{d}\alpha. \end{cases}$$

Now consider all the interpretations for this program:

In this diagram:

- Negations are represented as e.g. \bar{a} instead of $\neg a$; Stable models are denoted by shaded nodes as ab .
- Interpretations in $\langle x|$ are e.g. (a) and those in $|x\rangle$ are e.g. $\boxed{\bar{a}b}$. The remaining are simply denoted by e.g. $a\bar{b}$.
- The edges connect stable models with related interpretations. Up arrow indicate links to $|s\rangle$ and down arrows to $\langle s|$.
- The *weight propagation* sets:

$$w(abc) = w(ab)w(ac) = \alpha^2 d\bar{d},$$

$$w(\bar{a} \cdot \cdot) = w(\neg a) = \bar{\alpha},$$

$$w(a) = w(ab) + w(ac) = \alpha(d + \bar{d}) = \alpha,$$

$$w(b) = w(ab) = d\alpha,$$

$$w(c) = w(ac) = \bar{d}\alpha,$$

$$w(\emptyset) = w(ab) + w(ac) + w(\neg a) = d\alpha + \bar{d}\alpha + \bar{\alpha} = 1,$$

$$w(a\bar{b}) = 0.$$

- The total weight is

- ① Introduction
- ② Motivation
- ③ Resolution
- ④ Cases & Examples
 - Programs with disjunctive heads
 - Non-stratified programs**
- ⑤ Conclusions

The following LP is non-stratified, because has a cycle with negated arcs:

$$c_1 = a \vee \neg a,$$

$$c_2 = b \leftarrow \sim c \wedge \sim a,$$

$$c_3 = c \leftarrow \sim b.$$

This program has three stable models

$$s_1 = \{a, c\},$$

$$s_2 = \{\neg a, b\},$$

$$s_3 = \{\neg a, c\}.$$

The disjunctive clause $a \vee \neg a$ defines a set of **total choices**

$$\Theta = \{\theta_1 = \{a\}, \theta_2 = \{\neg a\}\}.$$

Looking into probabilistic interpretations of the program and/or its models, we define $\alpha = p(\Theta = \theta_1) \in [0, 1]$ and $p(\Theta = \theta_2) = \bar{\alpha}$. Since s_1 is the only stable model that results from $\Theta = \theta_1$, it is natural to extend $p(s_1) = p(\Theta = \theta_1) = \alpha$. However, there is no clear way to assign $p(s_2), p(s_3)$ since *both models result from the single total choice* $\Theta = \theta_2$. Clearly,

$$p(s_2 | \Theta) + p(s_3 | \Theta) = \begin{cases} 0 & \text{if } \Theta = \theta_1 \\ 1 & \text{if } \Theta = \theta_2 \end{cases}$$

but further assumptions are not supported *a priori*. So let's **parameterize** the equation above,

$$\begin{cases} p(s_2 | \Theta = \theta_2) = \beta \in [0, 1] \\ p(s_3 | \Theta = \theta_2) = \bar{\beta}, \end{cases}$$

in order to explicit our knowledge, or lack of, with numeric values and relations.

Now we are able to define the **joint distribution** of the boolean random variables A, B, C :

A, B, C	P	Obs.
$a, \neg b, c$	α	$s_1, \Theta = \theta_1$
$\neg a, b, \neg c$	$\bar{\alpha}\beta$	$s_2, \Theta = \theta_2$
$\neg a, \neg b, c$	$\bar{\alpha}\bar{\beta}$	$s_3, \Theta = \theta_2$
*	0	not stable models

where $\alpha, \beta \in [0, 1]$.

- 1 Introduction
- 2 Motivation
- 3 Resolution
- 4 Cases & Examples
- 5 Conclusions**

- We can use the basics of probability theory and logic programming to assign explicit *parameterized* probabilities to the (stable) models of a program.
- In the covered cases it was possible to define a (parameterized) *family of joint distributions*.
- How far this approach can cover all the cases on logic programs is (still) an issue *under investigation*.
- However, it is non-restrictive since *no unusual assumptions are made*.

- 1 Introduction
- 2 Motivation
- 3 Resolution
- 4 Cases & Examples
- 5 Conclusions

- An **atom** is $r(t_1, \dots, t_n)$ where
 - r is a n -ary predicate symbol and each t_i is a constant or a variable.
 - A **ground atom** has no variables; A **literal** is either an atom a or a negated atom $\neg a$.
- An **ASP Program** is a set of **rules** such as
$$h_1 \vee \dots \vee h_m \leftarrow b_1 \wedge \dots \wedge b_n.$$
 - The **head** of this rule is $h_1 \vee \dots \vee h_m$, the **body** is $b_1 \wedge \dots \wedge b_n$ and each b_i is a **subgoal**.
 - Each h_i is a literal, each subgoal b_j is a literal or a literal preceded by \sim and $m + n > 0$.
 - A **propositional program** has no variables.
 - A **non-disjunctive rule** has $m \leq 1$; A **normal rule** has $m = 1$; A **constraint** has $m = 0$; A **fact** is a normal rule with $n = 0$.
- The **Herbrand base** of a program is the set of ground literals that result from combining all the predicates and constants of the program.
 - An **interpretation** is a consistent subset (i.e. doesn't contain $\{a, \neg a\}$) of the Herbrand base.
 - Given an interpretation I , a ground literal a is **true**, $I \models a$, if $a \in I$; otherwise the literal is **false**.
 - A ground subgoal, $\sim b$, where b is a ground literal, is **true**, $I \models \sim b$ if $b \notin I$; otherwise, if $b \in I$, it is **false**.
